ABSTRACT

The African four-toed hedgehog is a small nocturnal mammal, characterized by a short-grooved brown or grey spine covering the dorsum of the body with a band of whitish fur running across their forehead, little is known about the reproductive biology of this animal. The present study aimed to evaluate the validity of immunohistochemistry in the differential labelling of the different cellular components of the testis of the African four-toed hedgehog. Paraffin-embedded testicular sections were stained by conventional histological technique using ten male African four-toed hedgehogs captured from the wild animals in Ibadan, Nigeria. Primary antibodies against alpha smooth muscle actin (α-SMA) and S-100 were applied on paraffin sections. The peritubular myoid cells, the testicular capsule and vascular endothelium expressed strong immunostaining for α-SMA. The spermatogenic cells, Sertoli and Leydig cells, peritubular myoid cells, the testicular capsule, straight tubules as well as rete testis and vascular endothelium all expressed positive immunostaining for S-100. α-SMA and S-100 proteins play active roles in cytoskeletal physiology of testis of the African four-toed hedgehog while S-100 protein plays additional role in the structural formation and maintenance of the blood-testis barrier during the process of spermatogenesis in the animal. It is concluded that α-SMA and S-100 proteins have active roles in the cytoskeletal structure of testis and physiology of the African four-toed hedgehogs.

Keywords: African four-toed hedgehog, Immunoreactivities, Spermatogenic cells, Sertoli cells, Testis.

INTRODUCTION

The order insectivore comprises several families that include shrews, moles, hedgehogs, solenodons, tenrecs and golden moles (Bedford et al., 2000). The African four-toed hedgehog (Atelerix albiventris), family Erinaceidae, widespread in West Africa, is an inhabitant of plains, savannas, and grassland (Kingdon, 1997). It has been described as a small nocturnal mammal, characterized by a short-grooved brown or grey spine covering the dorsum of the body with a band of whitish fur running across their forehead. The fifth toe on the hind feet, which is present in other species of Hedgehogs is reduced to vestigial hallux in this animal, hence the name “four-toed” and there is no sexual dimorphism (Reeve, 1994; Coker et al., 2018).

Despite its exploitation as a popular pet in the United States (Mori and O’Brien, 1997) as well as its use in biomedical research, the animal is listed as least concern in the IUCN red list category in view of its wide distribution and high tolerance to a degree of habitat modification (Cassola, 2016). It has been reported that Atelerix albiventris reaches sexual maturity in the wild at about 1-year of age but sexual maturity may be attained at 2-4 months (Smith, 1992; Symonds, 1999). Nevertheless, there is no record of its successful captive - breeding thus far (Santana et al., 2010).

Previous reports on the African four-toed hedgehog have focused on reproductive characteristics (Smith, 1992; Symonds, 1999; Bedford et al., 2000); skull morphometry (Couture et al., 2015; Girgiri et al., 2015); disease occurrence in captive animals (Gardhouse and Eshar, 2015) and appendicular skeleton morphology (Girgiri et al., 2016). Thus, there is paucity of research information on the reproductive biology of the African four-toed hedgehog (Olukole et al., 2020). In particular, nothing, to our knowledge, has been reported on the presence, localisation and activities of proteins in the testis of this animal.

This study was therefore aimed to investigate the immunohistochemical localization of alpha smooth muscle actin (α-SMA) and S-100 proteins in the testis of the African four-toed hedgehog as contribution to existing literature and possible improvement in the understanding of the testicular architecture and function and the captive-breeding programmes of this animal.
MATERIALS AND METHODS

Animals and tissues
Ten male African four-toed hedgehog, captured from the wild in Ibadan, Oyo State, Nigeria, between the months of May and October (wet season), 2016 were used for the study. The male hedgehogs had an externally visible penis, located in the mid-abdomen, but the testicles were recessed into pouches close to the anus (World Heritage Encyclopedia, 2017). Hedgehogs were anaesthetised with a subcutaneous injection of 20 mg/kg ketamine in the area of the back (Henke et al., 2007), sacrificed and the testis was retrieved immediately and fixed in buffered neutral formalin.

Ethical approval
Experiments were carried out according to the guidelines and approval of the institutional ethical committee of the University of Ibadan, Nigeria (UIACUREC: 12/17/05).

Histology and immunohistochemistry
Samples of the testes were fixed in Bouin’s fluid and embedded in paraffin blocks. Sections 2-4 µm thick were stained with Haematoxylin and Eosin (Alkafafy et al., 2012). The slides were then studied under a light microscope (Olympus BX63, Germany, with DP72 camera). Immunohistochemistry was carried out as reported by Aire and Ozegbe (2007). Briefly, paraffin-embedded tissues of testis were cut and mounted on slides pre-coated with polylysine. They were deparaffinised, rehydrated and heat-treated for antigen retrieval. To reduce endogenous peroxidase activity, sections were incubated for 5 min in hydrogen peroxide (3% in distilled water). In order to block non-specific binding sites, the slides were rinsed in a 0.01 m phosphate buffered saline solution (PBS, pH: 7.4), containing bovine serum albumen, for 5 minutes. Prior to immunostaining, validation trials for each of S-100 and α-smooth muscle actin antibodies in this species were carried out using four different dilutions (1: 50, 1: 100, 1:200 and 1:400). Immunostaining of slides were carried out for one hour at room temperature, using the LSAB-plus kit (Dakocytomation, Glostrup Co, Denmark) monoclonal antibodies against S-100 and α-smooth muscle actin at dilutions of 1:100 and 1:400, respectively. The slides were then rinsed in PBS followed by incubation for 15 minutes in a link antibody (Biotinylated secondary antibody, LSAB-plus kit; Dakocytomation) and then in peroxidase-labelled streptavidin. This was followed by addition of 3,3’-diaminobenzidine tetrachloride solution (DAB) from the LSAB+® kit to visualise antigen localization. Negative controls involved the primary antibody replaced by bovine serum albumen. Smooth muscle was used as a positive control for α-smooth muscle actin, while tonsillar tissue was used as positive controls for S-100. The testis sections were counterstained with hematoxylin for 30 seconds, washed in water, dehydrated through graded ethanol, cleared in xylene and mounted with DPX permanent mounting media (Sigma-Aldrich Co, MO, USA). Sections were then examined under light microscope. Immunoreactivities to S-100 and α-smooth muscle actin were designated as absent (-), weak (+), moderate (2+) and strong (3+) based on visual examination.

RESULTS

Histology
The testis was ensheathed by a capsule with seminiferous tubules of various sizes and shapes, mostly spherical to oval (Figure 1A). Wedged among adjacent seminiferous tubules was the interstitium containing interstitial Leydig cells and blood vessels. Highly-convoluted seminiferous tubules formed about 80% of testis tissue of the animal with each having a basement membrane lined with Sertoli cells as well as germ cells arranged in successive layers representing different stages of spermatogenesis and spermiogenesis (Figure 1B).

Immunohistochemistry
The main immunohistochemical findings are summarized in table 1.

Alpha smooth muscle actin (α-SMA)
Strong immunoreactivities to α-SMA were observed for the peritubular myoid cells, the testicular capsule and vascular endothelium (Figures 2A and B). The testicular capsule showed more intense reactivity in the inner than in the outer portions (Figure 2B). Moderate immunoreactivities to α-SMA were observed for the straight tubules as well as rete testis (Figures 2C and D). However, the spermatogenic cells, Sertoli cells and Leydig cells were immunonegative to α-SMA. Strong immunoreactivities to S-100 were observed for the peritubular myoid cells and testicular capsule (Figures 3B and D). The spermatogenic cells, Sertoli cells, Leydig cells, straight tubules as well as rete testis and vascular endothelium all expressed moderate immunoreactivities to S-100 (Figures 3A and C).
The histological features of the testis of the African four-toed hedgehog are similar to those reported for the African greater cane rat, *Thryonomys swinderianus* (Olukole et al., 2009; Olukole and Obayemi, 2010), the African giant rat, *Cricetomys gambianus* (Oke, 1982; Oke, 1988) and rodents generally (Bacha and Bacha, 2000; Massanyi et al., 2003; Young et al., 2006). Similar to the case in the African greater cane rat, contractile myoid cells were found lining the peritubular tissue of the seminiferous tubules of the African four-toed hedgehog (Olukole and Obayemi, 2010). However, unlike the case of the African greater cane rat, majority of the seminiferous tubules of the African four-toed hedgehog were highly convoluted (Olukole et al., 2009).

The present study is a new report on the localization of alpha smooth muscle actin (α-SMA) and S-100 in the testis of the African four-toed hedgehog. The more intense immunoreactivity to αSMA observed in the inner portion of the testicular capsule of the African four-toed hedgehog, suggests that contractile activity of the testicular capsule is greater in the inner than in the outer portions of the testicular capsule of the animal. Similar observation has been documented in the rat (Banks et al., 2006). Conversely, Abd-Elmaksoud (2009) reported αSMA-positive reaction to be more in the outer portion of the testicular capsule of the rabbit. αSMA has been reported to be widely distributed throughout the tunica albuginea of the testicular capsule in the avian species such as Sudani duck and pigeon (Abd-Elmaksoud, 2009). It can be inferred that the contractile smooth muscle arrangement observed in the testicular capsule of the African four-toed hedgehog may be essential in the movement of spermatozoa out of the testis of the animal.

The αSMA-positive reaction observed in the testicular peritubular tissue and vasculature in this study has been observed in several mammals and birds (Sekido and Lovell-Badge, 2013; Valdez et al., 2014; Domke et al., 2019). One of the functions of peritubular myoid cells has been shown to be the regulation of Sertoli cell functions in animals (Anthony, 1991). Sertoli cell’s stimulation of total protein by peritubular cells have linked to increases in androgen-binding protein production (Hadley et al., 1985).

Hence, peritubular myoid cells of the African hedgehog, due to its strong reactivity to αSMA are expected to collaborate with Sertoli cells in the structural formation and maintenance of the blood-testis barrier in the animal. Collectively, the positive immunoreactivities to αSMA observed for the testicular capsule, the peritubular myoid cells, straight tubules as well as the rete testis of the African four-toed hedgehog is suggestive of a collaborative contractile activity in the movement of spermatozoa produced in the seminiferous tubules into the excurrent ducts of the testis of the animal.

The strong immunoreactivities to S-100 protein observed for the peritubular tissue and Sertoli cells further shows the possibility of a collaborative function by the duo in the maintenance of the blood-testis barrier in the African hedgehog. Similarly, S-100 protein has been localized in the Sertoli cells of various animals includes bull, dog, boar, rat, rabbit, ram, stallion and boar (Riuzzi et al., 2011; Abd-Elmaksoud et al., 2014) as well as in the monkey, buffalo (Cruzana et al., 2003) and humans (Li et al., 2010; West and Watson, 2010). S-100 protein has been shown to regulate cell division and cell morphology in a calcium-dependent manner (Donato, 2001; Abd-Elmaksoud et al., 2014) Also, S-100 protein in the Sertoli cells is assumed to be involved in the microtubule assembly-disassembly as well as in the secretory, protective and absorptive functions of the Sertoli cells of mammals (Cruzana et al., 2003).

The S-100 positive reaction with spermatogenic and Leydig cells of the African four-toed hedgehog suggests that the protein is involved in the processes of spermatogenesis as well as steroidogenesis. S-100 positive reaction has been reported for the Leydig cells of turtle and mammals (Young et al., 2006; Olukole et al, 2018). However, the testicular germ cells as well as the Leydig cells of the rabbit have been shown to be immunonegative to S-100 (Abd-Elmaksoud et al., 2014).

The strong immunoreactivity to S-100 exhibited by the testicular vasculature in this study tallies with other studies that have shown that the endothelial cells of capillaries, veins, and lymphatic vessels are regularly S-100 protein immunoreactive in rat, rabbit, boar, ruminants, European bison and man (Michetti et al., 1985; Amselgruber et al., 1994; Czykier, 1999; Abd-Elmaksoud et al., 2014). Testicular S-100 protein has been reported serve in the prevention of cytoplasmic calcium overload which has been demonstrated to cause cellular apoptosis as well as the induction of mitochondria calcium overload thereby leading to testicular mitochondrial malfunctioning (Orrenius et al., 2003).

**CONCLUSION**

In conclusion, αSMA and S-100 proteins have active roles in the cytoskeletal structure of testis and physiology of the African four-toed hedgehogs while S-100 protein plays additional and complementary roles in the structural formation and maintenance of the blood-testis barrier as well as in steroidogenesis and spermatogenesis in the animal.
