**ABSTRACT**

As a dietary supplement for animals, *Moringa oleifera* is very useful because its leaves are very nutritious. *Moringa oleifera* leaves are rich in fats, proteins, vitamins, and minerals with antimicrobial effects. Leaf tea is used to treat ulcers in the stomach and diarrhea. Moringa leaves are considered healthy food sources and are recommended for anemia from malnutrition due to the high protein, fiber, and iron content of the leaves. *Moringa oleifera* leaves are primarily used for medicinal and human consumption purposes since they are abundant in antioxidants and other nutrients. Due to the low energy and digestibility of proteins, *Moringa oleifera* leaf meal supplementation increases feed intake and feed conversion ratio, as well as decreasing egg mass yield, percentage of egg production, and egg weight. More research in these areas is required to make full use of the potential advantages of the *Moringa oleifera* plant as layer feed.

**Keywords:** Layer chicken, Laying performance, Leaf meal, Moringa oleifera

**INTRODUCTION**

Chickens are a major and inexpensive source of animal protein, so poultry production plays a vital role in social and economic securities in developing countries (Olwande et al., 2010; Melesse et al., 2013). Nutrition and environmental factors affect the production output of poultry (Gakuya et al., 2014). Protein supplementation is very important for egg production, with the key sources being soya bean meal and fish meal (Gakuya et al., 2014).

In most developed countries, poultry production industries face the challenge of raising feed costs by 60-70% (Tesfaye et al., 2013). Modern poultry husbandry systems strive to achieve full benefit at the lowest cost of production. This situation has led to the need to look for cheap, locally available, and less competitive alternatives for some poultry feed ingredients, and in particular, protein sources (Gadzirayi et al., 2012). In this context, the best alternative protein source may be *Moringa oleifera* leaves.

Many parts of *Moringa oleifera* (leaves, fruits, immature pods, and flowers) are incorporated into typical human foods in many tropical and subtropical countries (Siddhuraju and Becker, 2003). *Moringa oleifera* is the supplement chosen as a leaf meal in animal diets (Siddhuraju and Becker, 2003). India, the Philippines, Ethiopia, and Sudan are widely known for the *Moringa oleifera* cultivation. The *Moringa oleifera* tree is cultivated in tropical Asia, Latin America, the Caribbean, the Pacific Islands, South Africa as well as West and East Florida (Fahey, 2005). In Ethiopia, the Moringa tree is called Shiferaw or Cabbage Tree and is usually found in the southern region.

As a feed for livestock, supplementation of *Moringa oleifera* is potentially beneficial, as its leaves are highly nutritious. The most nutritious components are Vitamin B complexes, Vitamin C, beta-carotene, Vitamin K, manganese, and protein, among other essential nutrients, present in *Moringa oleifera* leaves (Leone et al., 2015). *Moringa oleifera* leaves have high levels of fats, proteins, minerals, and vitamins and have antimicrobial properties (Onunkwo and George, 2015). Supplementing the diets of farm animals with *Moringa oleifera* was inadequate to increase production quality and health. Although *Moringa oleifera* has medicinal importance for the health of chickens, the supplementation of *Moringa oleifera* levels in the poultry diet is low due to the farmers’ and producers’ lack of knowledge (Mahfuz and Piao, 2019). *Moringa oleifera* has a high nutritional content, but there is little information on its use as a source of protein in the layer ration in poultry feeding. Consequently, data on the effects of feeding *Moringa oleifera* leaf meal (MOLM) is scarce when it comes to laying efficiency or egg production, egg quality and egg shelf life, chicken fertility, and hatchability (Alebachew et al., 2016). This review, therefore, intended to evaluate the role of *Moringa oleifera* leaf meal in layer chicken growth results.

**Nutritional value of Moringa oleifera**

*Moringa oleifera* is rich in protein, amino acids, carbohydrates, minerals, vitamins, and organic acids, and is known for its nutritional value (Raja et al., 2013). *Moringa* leaves have anti-bacterial, anti-inflammatory effects (Abbas et al., 2003).
Gastric ulcers and diarrhea are treated with *Moringa oleifera* leaf tea. Moringa leaves are safe food sources for those suffering from anemia due to malnutrition because of the high protein and fiber content and iron content (Abbas et al., 2018). The most nutritious component is the leaves of *Moringa oleifera*, which are an important source of Vitamin B complex, Vitamin C, beta-carotene pro-vitamin A, Vitamin K, manganese, and protein, among other essential nutrients (Mahfuz and Piao, 2019).

Compared to seeds, a greater quantity of minerals is found in *Moringa oleifera* leaves (Annongu et al., 2014). In reality, moringa is said to supply 7 times more vitamin C than oranges, 10 times more vitamin A than carrots, 17 times more calcium than drain, 9 times more protein than yoghurt, 15 times more potassium than bananas, and 25 times more press than spinach (Gopalakrishnan et al., 2016).

*Moringa oleifera*’s fresh leaves contain seven times the Vitamin C of oranges and four times the Vitamin A of carrots. However, *Moringa oleifera*’s dried leaves contain 10 times the Vitamin A and 1/2 times the Vitamin C of oranges (Mahmood et al., 2010). As an animal feed supplement, the leaves of *Moringa oleifera* are very useful as their leaves are highly nutritious. *Moringa oleifera* is an excellent source of vitamins and amino acids that are alleged to improve the immune system (Olugbemi et al., 2010). *Moringa oleifera* seeds and leaves contain all essential amino acids and, when compared to the prescribed amino acid pattern requirements for most farm animals, these are higher than sufficient amounts (Alikwe and Omotosho, 2013). The leaves of *Moringa oleifera* have between 16 and 19 amino acids, out of which 10 are known as essential amino acids (Sonkar et al., 2019).

**Phytochemical composition of *Moringa oleifera* leaf meal**

A high concentration of phytochemicals accumulates in plants, which can defend against free radical damage (Alagbe, 2019). Vitamins (A, C, and E), flavonoids, and tannins, have been found to have high levels of antioxidants, which have a variety of health benefits for humans and animals (Alagbe, 2019). The synergistic combination of these phytochemicals in *Moringa oleifera* causes an increase in feed intake, palatability, and disease prevention (Alagbe, 2019). A massive wide variety of bioactive compounds have been identified in *Moringa oleifera* (Martin et al., 2013). Vitamin-rich leaves, carotenoids, polyphenols, phenolic acids, flavonoids, alkaloids, glucosinolates, isothiocyanates, tannins, and saponins are the most commonly used parts of the plant (Leone et al., 2015). *Moringa oleifera* leaves are often used for medicinal and human nutrition purposes since they have high levels of antioxidants and other nutrients usually lacking in people living in undeveloped nations (Popoola and Obembe, 2013). *Moringa oleifera* leaves have been used to treat various diseases, ranging from malaria and typhoid fever to high blood pressure and diabetes (Sivasankari et al., 2014).

**Effect of *Moringa oleifera* leaf meal on the performance of layers**

Melesse et al. (2011) found that using *Moringa* stenopetala leaf meal in the diet of Rhode Island Red chicks resulted in a significant improvement (p < 0.05) in feed and crude protein consumption, average weight gain, feed efficiency ratios, and protein efficiency ratios as compared to the control diet. As a supplement for sunflower seed meal, the addition of 10 percent and 20 percent *Moringa oleifera* leaf meal to the laying hen diet significantly (p < 0.05) increased feed intake and dry matter feed intake and decreased the development of egg mass (Kakengi et al., 2007). As the amount of *Moringa oleifera* leaf meal increased, the percentage of egg production decreased. The feed conversion ratio (kg feed/kg egg) is improved when 20% *Moringa oleifera* leaf meal was added to the laying hen diet. At a level of 20%, the addition of 5% *Moringa oleifera* leaf meal significantly increased egg weight (p < 0.05) but leading to lower egg weight (Abbas, 2013).

The increase in feed intake and feed conversion ratio and the decrease in the production of egg mass, percentage of egg production, and egg weight at higher levels of *Moringa oleifera* leaf meal was mainly due to low energy and protein digestibility (Abbas, 2013). Olugbemi et al. (2010) noted that *Moringa oleifera* leaf meal supplementation had no
significant impact on feed consumption, feed conversion ratio, and laying percentage at levels of up to 10% in a cassava chip-based diet provided to laying hens. In contrast to the control diet (free of *Moringa oleifera* leaf meal and cassava chip), egg weight substantially increased as a result of the supplementation of *Moringa oleifera* leaf meal with cassava chip (Abbas, 2013).

Abou-Elezz et al. (2011) agreed that up to 10% of the use of *Moringa oleifera* leaf meal had no adverse effect on laying hens’ efficient output, but levels above that (15% and 20%) are expected to have adverse effects. *Moringa oleifera* leaf powder increases the number of eggs per week, egg weight, egg width, egg surface, yolk height, yolk weight, albumen weight, and yolk ratio in the layer diet of chickens by 2.5% and 5%, compared to the control diet (Ebenebe et al., 2013).

**Effect of *Moringa oleifera* leaf meal on the egg quality**

There was no difference between the control groups and dietary inclusion of *Moringa oleifera* leaves (p > 0.05) in terms of the Haugh units, eggshell intensity, or egg shape index (Durmus et al., 2004). The addition of *Moringa oleifera* leaf had no impact on the egg shape index, which is linked to eggshell intensity and egg grade (Ebenebe et al., 2013). Mabusels et al. (2018) discovered that adding 10% *Moringa oleifera* seed meal to layer diets increased shell thickness, compared to the control diet. However, both 5% and 7.5% *Moringa oleifera* seed meal supplementation had the same effect on eggshell thickness. With regard to the effect of different *Moringa oleifera* leaves on layer diet, lower levels of inclusion increased egg production and egg quality, but higher levels of inclusion resulted in lower productivity and lower quality indices in the Isa Brown Breed layer chickens (Ebenebe et al., 2013). The R2 value for the relationship between egg weight and MOL inclusion amount in the diet was 0.99. Increased MOL levels in the diet resulted in a decrease in egg weight, egg width, yolk weight, and yolk (p < 0.05), but MOL had no effect on egg volume, yolk duration, yolk index, or shell weight and thickness (Raphael et al., 2015).

Increased levels of MOLM did not affect feed consumption, weight gain, customer acceptance of boiled eggs, and egg weight (p ≥ 0.05, Gakuya et al., 2014). In terms of the impact of different MOL levels on layer diet, MOL inclusion at lower levels improved egg production and egg quality, but higher levels of inclusion resulted in lower productivity and lower quality indices of Isa Brown Breed layers (Ebenebe et al., 2013). There was, however, no substantial difference between the eggs from MOLM diets and those from supermarkets in the egg yolk color ratings (Gakuya et al., 2014). There are no major variations in egg weights from layers of *Moringa oleifera* leaf and twig meals at levels ranging from 0.2% to 0.8% (Paguia et al., 2014).

**Table 3. Effects of feeding various levels of *Moringa oleifera* leaf meal as a replacement for soybean meal on dual-purpose of egg quality in Koochoek hens**

**Effect of *Moringa oleifera* leaf meal on fertility and hatchability**

*Moringa oleifera* used as an alternative feed ingredient in the layer ration showed a non-significant effect on fertility, hatchability, and embryonic mortality (Etalem et al., 2014). Moyo et al. (2011) mentioned higher levels of zinc and Vitamin E in *Moringa oleifera* leaf played a beneficial role in egg hatchability. Likewise, Durmus et al. (2004) noted increased hatchability with increasing zinc concentration in the diets of Brown parent stock layers. Moringa contains large amounts of iron, calcium, and phosphorus, and Vitamin C is moderately high (Agbaje et al., 2007). Adesola et al. (2012) reported improved hatchability in the diets of indigenous Venda hens as a result of ascorbic acid supplementation. However, the relatively poor hatchability and higher embryonic mortality observed in the control group may be due to a lack of critical nutrients, such as zinc and Vitamin E, which are necessary for better hatchability (Mahmood and Al-Daraji, 2011).
Effects of *Moringa oleifera* on health status in laying hens

In determining the health status of chickens the analysis of blood parameters is incredibly important (Mahfuz and Piao, 2019). In line with Aye and Adegun (2013), higher levels of albumin levels were observed in laying hens fed with 3% *Moringa* leaf meal, compared to the control group, but the number of white blood cells (WBCs), red blood cells, lymphocytes, and packed cell volume were lower than the control diets in Moringa-fed groups. The antimicrobial activity of the phytochemicals in *Moringa* leaves may be attributed to the fact that *Moringa*-fed chickens have fewer WBCs and lymphocytes. A high WBC count is commonly linked to an infection caused by bacteria in the host (Mahfuz and Piao, 2019). The findings of this study indicated that *Moringa* pod meal supplementation was found to have lower serum cholesterol levels (Mahfuz and Piao, 2019). Lower plasma levels of malondialdehyde (MDA) and higher glutathione peroxidase have been linked to higher antioxidant activity in laying hens fed *Moringa* leaf meal (Lu et al., 2016). Plasma total protein levels were dietary 5% higher after *Moringa* leaf meal supplementation, which is a good predictor of liver synthetic activity. Furthermore, lower plasma uric acid indicated that supplemented laying hens retained more protein (Lu et al., 2016). Increased antioxidant enzyme activity and lower MDA levels in plasma and egg yolks indicated that *Moringa* supplementation could improve antioxidant activity and *Moringa oleifera* has strong phytobiotic properties.

CONCLUSION

In developing countries, poultry production plays a significant socio-economic role since chickens are an important and inexpensive source of animal protein. As a feed for livestock, supplementation of *Moringa oleifera* is potentially beneficial and its leaves are highly nutritious. The most nutritious components are Vitamin B complexes, Vitamin C, beta-carotene, Vitamin K, manganese, and protein, among other essential nutrients that are present in *Moringa oleifera* leaves. The increase in feed intake and feed conversion ratio and the decrease in the production of egg mass, percentage of egg production, and egg weight at higher levels of *Moringa oleifera* leaf meal were mainly due to low energy and protein digestibility. The effect of different *Moringa oleifera* leaf levels on layer diet, lower levels of inclusion increased egg production and egg quality, but higher levels of inclusion resulted in lower productivity and lower quality indices in the Isa Brown Breed layer chickens. *Moringa oleifera* leaves are mostly used both for medicinal and human nutrition purposes since they are rich in antioxidants and other nutrients, which are usually deficient in people living in undeveloped countries. More research in these areas is required in order to make full use of the potential advantages of the *Moringa oleifera* plant as layer feed.
