ABSTRACT

Owners of dogs with cancer are often offered chemotherapeutic treatment. However, clients who seek veterinary care for pets with cancer are often concerned about the potential negative impact of chemotherapeutic treatments on their animals' quality of life. The purpose of this retrospective case series was to investigate the delayed acute effects of chemotherapy drugs in dogs receiving cancer treatment and their owners’ opinions regarding chemotherapy acceptance by their pet. In this study, 292 dogs that were treated with chemotherapy as a definitive and/or adjuvant treatment for cancer. Medical records were reviewed to determine the chemotherapy agent used and if they had any delayed adverse effects or not. Side effects were classified according to VCOG-CTCAE grading of adverse effect severity veterinary co-operative oncology group. Lomustine, carboplatin, vincristine, doxorubicin, cyclophosphamide, mitoxantrone, and vinblastine were administered in 16%, 20%, 15%, 18%, 16%, 8%, and 7% of the cases respectively. The most common adverse effects were neutropenia (22%), vomiting (21%), diarrhea (20%) and inappetence (20%). Cyclophosphamide and vincristine were the agents that had caused more adverse gastrointestinal effects, while lomustine was the drug that had caused more hematologic effects. In some dogs receiving lomustine and carboplatin, neutropenia (some of them severe) had occurred as early as in the sixth day. According to the current grading system of adverse effects induced by chemotherapy, general tolerance to chemotherapy is referred to as grade 1, which was observed in 83% of the cases. Owner opinion was positive in most cases, and 77% of the owners had evaluated that the treatment was well tolerated by their dogs. In contrast, 8% of the treatments were poorly tolerated and they had negatively impacted the affected dogs' quality of life. Based on the data examined, we would recommend that gastrointestinal adverse effects must be prevented with antiemetic medication, especially in dogs receiving cyclophosphamide, vincristine, carboplatin and doxorubicin. Hematologic profile must be performed as early as in the 6-7th day after lomustine and carboplatin, as severe neutropenia can occur. Adverse chemotherapy effects may occur in about 20-25% of canine patients.

Influence of Enzymatic and Mechanical Liquefaction of Seminal Plasma on Freezability of Dromedary Camel Semen.

ABSTRACT
This study aimed to investigate the efficiency of mechanical and enzymatic elimination of semen viscosity in adult dromedary camel bulls’ semen on cryopreservation potential of spermatozoa. The researchers examined three different treatments for viscosity elimination; STR, WOB, and MSTR and WOB in the SMT. These results clarified that both enzymatic and mechanical methods have a significantly (P < 0.05) varying with body condition scores but it did not significantly (P > 0.05) vary with age groups of the animals. This study demonstrated the prevalence of bovine tuberculosis, it recognized as one of the most important threats to humans and animals causing mortality, morbidity and economic losses. Members of the Mycobacterium complex group cause tuberculosis, it detected only 2.7% (8/300) with visible lesions and there was poor agreement (kappa=0.09) with the prevalence of the disease determined to have been at 12.3%, 2% and 3.3%, respectively. The prevalence of the disease was significantly (P < 0.05) varying with body condition scores but it did not significantly (P > 0.05) vary with age groups of the animals.

ABSTRACT
Routine and detailed meat inspection methods used to detect lesions. Three hundred cattle inspected; their body condition scores and ages recorded before slaughtering. Of the total animals, 5.7% (17/300) had lesions of tuberculosis. Out of these, routine abattoir inspection had detected only 2.7% (8/300) with visible lesions and there was poor agreement (kappa=0.09) with the prevalence of the disease determined to have been at 12.3%, 2% and 3.3%, respectively. The prevalence of the disease was significantly (P < 0.05) varying with body condition scores but it did not significantly (P > 0.05) vary with age groups of the animals.
